

NON-ISOMORPHIC PURE GALOIS-EISENSTEIN RINGS

ALEXANDRE FOTUE TABUE AND CHRISTOPHE MOUAHA

ABSTRACT. Let n, r, e, s be positive integers and the prime p , the finite local principal ideals ring of parameters (p, n, r, e, s)

$$\text{GR}(p^n, r)[x]/(x^e - p\mathbf{u}, x^s),$$

is defined by an invertible element $\mathbf{u}$ of the Galois ring $\text{GR}(p^n, r)$ of characteristic p^n of order p^{nr} . It is called Galois-Eisenstein ring of parameters (p, n, r, e, s) . A basic problem, which seems to be very difficult is to determine all non-isomorphism pure Galois-Eisenstein rings of parameters (p, n, r, e, s) . In this paper, this isomorphism problem for pure Galois-Eisenstein rings of parameters (p, n, r, e, s) is investigated.

Keywords: Galois field, Galois ring.

AMS Subject Classification: 13Exx, 13M05, 13M10, 13Hxx, 13B05

1. INTRODUCTION

Throughout this paper, all rings are finite, associative, commutative with $1 (\neq 0)$. For a ring R , we denote by $R^\times$ be the set of invertible elements of R , and $J(R)$ the Jacobson radical of R . Let r, n , and p denote positive integers, p a prime, the residue class ring $\mathbb{Z}/p^n\mathbb{Z}$ of integers modulo p^n with p prime and $n > 1$ and let $\text{GR}(p^n, r)$ denote the (unique up to isomorphism) Galois extension of degree r of the ring $\mathbb{Z}/p^n\mathbb{Z}$ of integers mod p^n . To begin, let $f \in (\mathbb{Z}/p\mathbb{Z})[x]$ be a primitive irreducible polynomial of degree r . Then there is a unique monic polynomial $f_n \in (\mathbb{Z}/p^n\mathbb{Z})[x]$ of degree r such that $f \equiv f_n \pmod{p}$, and f_n divides $x^{p^r-1} - 1$ in $(\mathbb{Z}/p^n\mathbb{Z})[x]$. Let ξ be a root of f_n , so that $\xi^{p^r-1} = 1$. The Galois ring $\text{GR}(p^n, r)$ is defined to be $(\mathbb{Z}/p^n\mathbb{Z})[\xi]$. Moreover, $\text{GR}(p^n, r)$ is local ring with $J(\text{GR}(p^n, r)) = (p)$ and the order of multiplicative subgroup $\Gamma_p(r)^* := \langle \xi \rangle$ of $\text{GR}(p^n, r)^\times$ is $p^r - 1$. The set $\Gamma_p(r) := \Gamma_p(r)^* \cup \{0\}$ is called *Teichmüller set* of $\text{GR}(p^n, r)$. The Galois ring $\text{GR}(p^n, r)$ depends only on p, n and r .

A ring R is a *Galois-Eisenstein ring of parameters* (p, n, r, e, s) if $\text{GR}(p^n, r)$ is the largest Galois ring contained in R and all ideals form the chain 1.1

$$\{0\} = (\theta^s) \subsetneq (\theta^{s-1}) \subsetneq \cdots \subsetneq (\theta) = J(R) \subsetneq R. \quad (1.1)$$

Since $J(\text{GR}(p^n, r)) = (p)$, there exists an integer e such that $(\theta^e) = pR$. The integer s the *nilpotency index* of $J(R)$, the Jacobson radical of R , the integer

e ramification index of R . According to the Theorem 17.5 of [4], a GE-ring of parameters (p, n, r, e, s) is isomorphic to the ring

$$\text{GR}(p^n, r)[x]/(x^e - p\mathbf{u}(x); x^s) \quad (1.2)$$

where $\mathbf{u}(x) := \mathbf{u}_{e-1}x^{e-1} + \cdots + \mathbf{u}_1x + \mathbf{u}_0 \in \text{GR}(p^n, r)[x]$, with $\mathbf{u}_0 \in \text{GR}(p^n, r)^\times$. The polynomial $x^e - p\mathbf{u}(x)$ is an *associated Eisenstein polynomial* to the GE-ring 1.2. W. Clark and J. Liang shown in Lemma 2. of [1] that when $n > 1$, an element θ in R is a root of an Eisenstein polynomial of degree e over $\text{GR}(p^n, r)$ if and only if $J(R) = (\theta)$. We say that a GE-ring of the form (1.2) is *pure* if $\mathbf{u}(x) = \mathbf{u}_0 \in \text{GR}(p^n, r)^\times$.

Clark and Liang shown in [1] that, if $p \nmid e$ then pure GE-rings in the form (1.2) are pure and they enumerate all non-isomorphic pure GE-rings and when $p \mid e$, Clark and Liang shown in [1] that there are GE-rings which are not pure. Moreover, Xiang-Dong Hou in [2] gave the number of all non-isomorphic pure GE-rings, when $n = 2$ or $p \mid e$, $p^2 \nmid e$ and $(p-1) \nmid e$. In this paper, the main goal is the determination all non-isomorphic pure GE-ring of parameters (p, n, r, e, s) , when $(p-1) \nmid e$.

The paper is organized as follows. In Section 2, we review some basic facts about Galois rings and pure GE-rings of parameters (p, n, r, e, s) to be used in sequel. In Section 3, we determine all non-isomorphic pure GE-rings of parameters (p, n, r, e, s) .

2. PRELIMINARIES

Let R be a pure GE-ring of parameters (p, n, r, e, s) . Let

$$\mathcal{L}_e(R) := (R^\times)^e \cap (\text{GR}(p^n, r))^\times$$

be a multiplicative subgroup of $\text{GR}(p^n, r)^\times$, where $(R^\times)^e := \{\mathbf{u}^e : \mathbf{u} \in R^\times\}$. The aim of this section is the determination of the integer $\flat(e) \in \{1; 2; \cdots; n\}$ such that

$$\mathcal{L}_e(R) = (\Gamma_p(r)^*)^e \cap (1 + p^{\flat(e)}\text{GR}(p^n, r)). \quad (2.1)$$

2.1. Galois Rings. The theory of Galois Rings was firstly developed by W. Krull (1924) and the reader will find in the monograph [7], more information about on Galois rings quoted. For this subsection, we gather the results on Galois rings allowing to determine the integer $\flat(e)$. A finite local ring of characteristic p^n is called Galois ring $\text{GR}(p^n, r)$ of characteristic p^n of rank r , if its Jacobson radical is generated by p . It is obvious that $\text{GR}(p^n, 1) = \mathbb{Z}/p^n\mathbb{Z}$ and $\text{GR}(p, r) = \text{GF}(p^r)$, where $\text{GF}(p^r)$ is the Galois field of the size p^r .

Let $f_n \in (\mathbb{Z}/p^n\mathbb{Z})[x]$ be a monic polynomial of degree r such that

$$f_n \bmod p \in (\mathbb{Z}/p\mathbb{Z})[x]$$

is irreducible over $\mathbb{Z}/p\mathbb{Z}$ and f_n divides $x^{p^r-1} - 1 \pmod{p^n}$. In [5], an algorithm allows to compute the polynomial f_n is given. Let ξ be a root of f_n . Then $\text{GR}(p^n, r) = (\mathbb{Z}/p^n\mathbb{Z})[\xi]$ and $\Gamma_p(r)^* := \langle \xi \rangle$ is the unique cyclic subgroup of order $p^r - 1$ of multiplicative group $\text{GR}(p^n, r)^\times$ isomorphic to cyclic multiplicative group $\text{GF}(p^r)^*$. The Teichmüller set $\Gamma_p(r)$ of $\text{GR}(p^n, r)$ forms a complete system of representatives modulo p in $\text{GR}(p^n, r)$.

The following proposition gives the immediate proprieties of the Teichmüller set of the Galois ring $\text{GR}(p^n, r)$.

Proposition 1. *Let ξ be a generator of $\Gamma_p(r)^*$. Then*

(1) $\text{GR}(p^n, r) \subseteq \text{GR}(p^n, r')$ if and only if

$$\Gamma_p(r) \subseteq \Gamma_p(r')$$

if and only if r divides r' ;

(2) $\Gamma_p(r) \cap \Gamma_p(r') = \Gamma_p(\gcd(r, r'))$;

(3) $(\Gamma_p(r)^*)^e = \langle \xi^e \rangle$ and the order of $\langle \xi^e \rangle$ is $\frac{p^r-1}{\gcd(p^r-1, e)}$.

Example 1. *The monic polynomials $f := x^2 + x + 2$ is irreducible over $\text{GF}(3)$. We denote by α the root of f . Then $\text{GF}(3)(\alpha)$ is the Galois field with 9 elements. Moreover, the monic polynomial $f_2 := x^2 - 5x - 1 \in (\mathbb{Z}/9\mathbb{Z})[x]$ such $f_2 \pmod{3} = f$ and f_2 divides $x^8 - 1$ in $(\mathbb{Z}/9\mathbb{Z})[x]$. We then construct the Galois ring $\text{GR}(9, 2)$ and $\text{GR}(9, 2) = (\mathbb{Z}/9\mathbb{Z})[\xi]$, where $\xi^2 = 5\xi + 1$. Thus the Teichmüller set of the Galois ring $\text{GR}(9, 2)$ is*

$$\Gamma_3(2) = \{0, 1, \xi, \xi^2 (= 5\xi + 1), \xi^3 (= 8\xi + 5), \xi^4 (= 8), \xi^5 (= 8\xi), \xi^6 (= 4\xi + 8), \xi^7 (= \xi + 4)\},$$

$$\text{and } (\Gamma_3(2)^*)^{18} = (\Gamma_3(2)^*)^2 = \langle \xi^2 \rangle = \{1, 5\xi + 1, 8\}.$$

The following lemma gives the immediate proprieties of a complete residue system modulo p^ℓ , where $\ell \in \{0, 1, \dots, n\}$.

Lemma 2.1. *Let ξ be a generator of $\Gamma_p(r)^*$ and $\ell \in \{0, 1, \dots, n\}$, we consider the set*

$$\mathcal{R}_r(\ell) := \left\{ \sum_{i=0}^{\ell-1} \xi_i p^i \in \text{GR}(p^n, r) : \xi_i \in \Gamma_p(r) \right\} \quad (2.2)$$

and by convention, we adopt $\mathcal{R}_r(0) := \{0\}$. Then

- (1) $\mathcal{R}_r(1) = \Gamma_p(r)$ and $\mathcal{R}_r(n) = \text{GR}(p^n, r)$;
- (2) $\mathcal{R}_r(\ell)$ forms a complete residue system modulo p^ℓ in $\text{GR}(p^n, r)$;
- (3) for each $\alpha \in \text{GR}(p^n, r)$, for each $\ell \in \{0; 1; 2; \dots; n\}$, there exists a unique $(\gamma; \beta)$ in $\mathcal{R}_r(\ell) \times \mathcal{R}_r(n - \ell)$, such that $\alpha = \gamma + p^\ell \beta$.

We remark that

$$\mathcal{R}_r(0) \subset \mathcal{R}_r(1) \subset \dots \subset \mathcal{R}_r(n). \quad (2.3)$$

Proposition 2. *The automorphism group of the ring $GR(p^n, r)$ is*

$$\text{Aut}(GR(p^n, r)) := \langle \{\sigma_p : \xi \mapsto \xi^p\} \rangle,$$

and for all $\xi_i \in \Gamma_p(r)$,

$$\sigma \left(\sum_{i=0}^{n-1} \xi_i p^i \right) = \sum_{i=0}^{n-1} \sigma(\xi_i) p^i.$$

Moreover, the groups $\text{Aut}(GR(p^n, r))$ and $\{0; 1; \dots; r-1\}$, are isomorphic and for all $j \in \{0; 1; \dots; r-1\}$,

$$\{x \in \Gamma_p(r) : \sigma_p^j(x) = x\} = \Gamma_p(\gcd(r, j)).$$

We remark that if $\gcd(r, j) = 1$ then $\{x \in \Gamma_p(r) : \sigma_p^j(x) = x\} = \mathbb{Z}/p^n\mathbb{Z}$.

Example 2. *Consider the Galois ring*

$$GR(9, 2) = (\mathbb{Z}/9\mathbb{Z})[\xi],$$

where $\xi^2 = 5\xi + 1$. Thus the Teichmüller set of the Galois ring $GR(9, 2)$ is

$$\Gamma_3(2) = \{0, 1, \xi, 5\xi + 1, 8\xi + 5, 8, 8\xi, 4\xi + 8, \xi + 4\}.$$

The Galois group of the ring $GR(p^n, r)$ is

$$\text{Aut}(GR(9, 2)) = \{Id, \sigma_3 : \xi \mapsto \xi^3\}$$

and

$$\{x \in \Gamma_3(2) : \sigma_3(x) = x\} = \Gamma_3(\gcd(2, 1)) = \mathbb{Z}/9\mathbb{Z}.$$

The structure of group of invertible elements of $GR(p^n, r)$ is given by the following theorem.

Theorem 2.2. ([7] Theorem 14.11]) *Let $GR(p^n, r)^\times$ be the group of invertible elements of $GR(p^n, r)$. Then $GR(p^n, r)^\times$ is the internal direct product of subgroups $\Gamma_p(r)^*$ and $1 + pGR(p^n, r)$. Moreover,*

(1) *If p is odd or if $p = 2$ and $n \leq 2$, then*

$$1 + pGR(p^n, r) \cong (\mathbb{Z}/(p^n))^r, \quad (2.4)$$

(2) *if $p = 2$ and $n \geq 3$, then*

$$1 + pGR(p^n, r) \cong GF(2) \times (\mathbb{Z}/(2^{n-2})) \times (\mathbb{Z}/(2^{n-1}))^{r-1}. \quad (2.5)$$

The Theorem 2.2 has as a consequence the following corollary and this corollary gives a simple expression of the subgroup $(1 + pGR(p^n, r))^{p^i}$ of $1 + pGR(p^n, r)$.

Corollary 1. *Let i be an integer and p is a prime. If p odd or if $p = 2$ and $n \leq 2$, then*

$$(1 + p\text{GR}(p^n, r))^{p^i} = 1 + p^{i+1}\text{GR}(p^n, r). \quad (2.6)$$

2.2. Pure Galois-Eisenstein Rings. Let R be a pure Galois-Eisenstein ring (short: pure GE-ring) of parameters (p, n, r, e, s) . Then there exists $\mathbf{u} \in \text{GR}(p^n, r)^\times$ such that $R = \text{GR}(p^n, r)[x]/(x^e - p\mathbf{u}; x^s)$. The writing

$$\text{GE}(\mathbf{u}) := \text{GR}(p^n, r)[x]/(x^e - p\mathbf{u}; x^s) \quad (2.7)$$

means that $\text{GE}(\mathbf{u})$ is a GE-ring of parameters (p, n, r, e, s) defines by the invertible element $\mathbf{u} \in \text{GR}(p^n, r)^\times$. In the sequel, we write $\text{GE}(\mathbf{u}) = \text{GR}(p^n, r)[\theta]$, such that $\theta^e = p\mathbf{u}$ and $\theta^s = 0$, but $\theta^{s-1} \neq 0$, for denote the pure Galois-Eisenstein ring of parameters (p, n, r, e, s) . We obvious that the Jacobson radical of $\text{GE}(\mathbf{u})$ is (θ) .

Lemma 2.3. *Let R be a pure Galois-Eisenstein ring of parameters (p, n, r, e, s) . Then the group of invertible elements $R^\times$ of R is the internal direct product of subgroups $\Gamma_p(r)^*$ and $1 + J(R)$.*

The following theorem gives the structure of subset

$$\mathcal{L}_e(R) := (R^\times)^e \cap (\text{GR}(p^n, r))^\times \quad (2.8)$$

of group of invertible elements $\text{GR}(p^n, r)^\times$. This is the main result in this section.

Theorem 2.4. *Let R be a pure Galois-Eisenstein ring of parameters (p, n, r, e, s) such that $s = (n-1)e + t$, $0 \leq t \leq e$ and $(p-1) \nmid e$. Then there exists an integer $\mathfrak{b}(e) \in \{1; 2; \dots; n\}$ such that*

$$\mathcal{L}_e(R) = \langle \eta \rangle \cdot (1 + p^{\mathfrak{b}(e)}\text{GR}(p^n, r)),$$

where

$$\mathfrak{b}(e) = \begin{cases} 1, & \text{if } t \leq \frac{e}{p} \text{ and } n = 2; \\ \min\{\omega + 1; n\}, & \text{if } t > \frac{e}{p} \text{ and } n = 2 \text{ or } n \neq 2, \end{cases}$$

where $\omega := \max\{i \in \mathbb{N}^* : p^i \mid e\}$.

Proof 1. *The size of the multiplicative group $1 + J(R)$ is a power of p , therefore*

$$(1 + J(R))^{p^e} = 1 + J(R)^{p^\omega}$$

and $\mathfrak{b}(e) = \mathfrak{b}(\omega)$.

By Theorem 2.2 and Lemma 2.3.,

$$\mathcal{L}_e(R) = \left(\Gamma_p(r) \cdot (1 + J(R))^{p^\omega} \right) \cap \left(\Gamma_p(r) \cdot (1 + p\text{GR}(p^n, r)) \right),$$

It follows that

$$\mathcal{L}_e(R) = \langle \eta \rangle \cdot \left((1 + J(R))^{p^\omega} \cap (1 + p\text{GR}(p^n, r)) \right),$$

in according by Lemma 2.1., we have $\left(\Gamma_p(r)^* \right)^e = \langle \eta \rangle$. It suffices to determine the integer $\flat(e)$ such that

$$(1 + J(R))^{p^\omega} \cap (1 + p\text{GR}(p^n, r)) = 1 + p^{\flat(e)}\text{GR}(p^n, r).$$

We write

$$(1 + J(R))^{p^\omega} \cap (1 + p\text{GR}(p^n, r)) = \mathcal{L}_1 \cup \mathcal{L}_2,$$

where

$$\mathcal{L}_1 = \left\{ (1 + \theta^b \varepsilon)^{p^\omega} \in 1 + p\text{GR}(p^n, r) : b \geq e ; \varepsilon \in R^\times \right\},$$

$$\mathcal{L}_2 = \left\{ (1 + \theta^b \varepsilon)^{p^\omega} \in 1 + p\text{GR}(p^n, r) : 1 \leq b < e ; \varepsilon \in R^\times \right\}.$$

Let b be an integer and $\varepsilon \in R^\times$. On the one hand, suppose that $b \geq e$. We have

$$1 + \theta^b \varepsilon \in 1 + pR$$

and

$$(1 + \theta^b \varepsilon)^{p^\omega} \in (1 + pR)^{p^\omega} \subseteq 1 + p^{\omega+1}R.$$

Thus

$$\begin{aligned} (1 + \theta^b \varepsilon)^{p^\omega} \in (1 + p^{\omega+1}R) \cap (1 + p\text{GR}(p^n, r)) &= 1 + p^{\omega+1}\text{GR}(p^n, r) \\ &= (1 + p\text{GR}(p^n, r))^{p^\omega}. \end{aligned}$$

Since

$$(1 + p\text{GR}(p^n, r))^{p^\omega} \subseteq \mathcal{L}_1,$$

we have

$$\mathcal{L}_1 = (1 + p\text{GR}(p^n, r))^{p^\omega},$$

on the other hand, suppose that $b < e$, we develop the following expression $(1 + \theta^b \varepsilon)^{p^\omega}$ and we obtain:

$$\begin{aligned} (1 + \theta^b \varepsilon)^{p^\omega} &= 1 + \sum_{l=1}^{p^\omega-1} \binom{l}{p^\omega} (\theta^b \varepsilon)^l + (\theta^b \varepsilon)^{p^\omega}, \text{ since } l = jp^i \text{ and } p \nmid j; \\ &= 1 + \sum_{i=1}^{\omega-1} \sum_{\substack{jp^i \leq p^\omega-1 \\ p \nmid j}} \binom{jp^i}{p^\omega} (\theta^b \varepsilon)^{jp^i} + (\theta^b \varepsilon)^{p^\omega}, \end{aligned}$$

since

$$p^{\omega-i} \mid \binom{jp^i}{p^\omega}$$

and

$$p^{\omega-i+1} \nmid \binom{jp^i}{p^\omega};$$

thus

$$(1 + \theta^b \varepsilon)^{p^\omega} = 1 + \sum_{i=1}^{\omega-1} \theta^{e(\omega-i)+bp^i} \varepsilon_i + \theta^{bp^\omega} \varepsilon^{p^\omega},$$

where $\varepsilon_i \in R^\times$. We write $h(b, i) := e(\omega - i) + bp^i$ and

$$h(b) := \min\{e(\omega - i) + bp^i : 0 \leq i < \omega\}.$$

If $(p - 1) \nmid e$, then $h(b, i) \neq h(b, i + 1)$. Thus there exists a unique $\iota \in \{0; \dots; \omega - 1\}$ such that $h(b) = h(b, \iota)$. Therefore, there exists $\varepsilon_b \in R^\times$ such that

$$(1 + \theta^b \varepsilon)^{p^\omega} = 1 + \theta^{h(b)} \varepsilon_b + \theta^{bp^\omega} \varepsilon^{p^\omega}.$$

This forces that $h(b) \geq s$, and $bp^\omega \equiv 0 \pmod{e}$. We have $a \in \mathbb{N}^*$ such that $(pu)^a \varepsilon^{p^\omega} \in p\text{GR}(p^n, r)$. We obtain,

$$\mathcal{L}_2 = \begin{cases} 1 + p\text{GR}(p^n, r), & \text{if } n = 2 \text{ and } t \leq \frac{e}{p}; \\ \{1\}, & \text{if } n \neq 2 \text{ or } n = 2 \text{ and } t > \frac{e}{p}. \blacksquare \end{cases}$$

Example 3. Let R be a GE-ring of parameters $(3, 2, 2, 18, 25)$.

Then by Theorem 2.2, $b(2) = 2$. Thus

$$\begin{aligned} \mathcal{L}_9(R) &= \langle \xi^2 \rangle \cdot (1 + 3^8 \text{GR}(9, 2)) \\ &= \{1, \xi^2, \xi^4\}, \end{aligned}$$

where $\Gamma_3(2)^* = \langle \xi \rangle$ and $\xi^2 = 5\xi + 1$.

3. MAIN RESULT

In this section, we determine the pure GE-rings of parameters (p, n, r, e, s) . Note when $n = 1$, $R = GF(p^r)/(x^e)$. Such rings need no classification, so we will suppose that $n \geq 2$. The isomorphism problem for pure GE-rings with given parameters (p, n, r, e, s) mentions by A. A. Nechaev in [6] and T. G. Gazaryan in [3], shown that pure GE-rings $GE(1)$ and $GE(2)$ of parameters $(3, 2, 1, 2, 3)$ are non-isomorphic rings with isomorphic additive and multiplicative groups.

Let $\sim$ be the equivalence relation defined on $GR(p^n, r)^\times$ by

$$\mathbf{u} \sim \mathbf{v} \Leftrightarrow GE(\mathbf{u}) \cong GE(\mathbf{v}), \quad (3.1)$$

where $\mathbf{u}, \mathbf{v} \in GR(p^n, r)^\times$.

Let σ be a generator of $\text{Aut}(GR(p^n, r))$, and the multiplicative subgroup

$$\mathcal{L}_e(R) = \langle \eta \rangle \cdot (1 + p^{b(e)} GR(p^n, r))$$

of $GR(p^n, r)^\times$ and η a generator of $(\Gamma_p(r)^*)^e$. Consider

$$U_r(b(e)) := \langle \chi \rangle + p\mathcal{R}_r(\partial(e) - 1), \quad (3.2)$$

where $\partial(e) = \min\{\partial(e); n - 1\}$.

We write $\chi := \xi^{\frac{p^r-1}{d}}$ and $d := \gcd(p^r - 1; e)$. Since $\gcd(d; (\frac{p^r-1}{d})) = 1$, then $\langle \chi \rangle \cdot \langle \eta \rangle = \Gamma_p(r)^*$.

The isomorphic GE-rings have the same parameters, but there are non-isomorphic GE-ring with the same parameters. The following example illustrates the isomorphism problem for the GE-rings.

Example 4. *T. G. Gazaryan, given in [3], two GE-rings of parameters $(3, 2, 1, 2, 3)$ $GE(1) = (\mathbb{Z}/9\mathbb{Z})[\theta]$ and $GE(2) = (\mathbb{Z}/9\mathbb{Z})[\delta]$ as an example of non-isomorphic commutative chain rings. We have $\theta^2 = 3, \delta^2 = 6$, and $\theta^3 = \delta^3 = 0$.*

Then the radical Jacobson are:

$$J(GE(1)) = (\theta) = \{0; 3; 6; \theta; 3\theta\}$$

and

$$J(GE(2)) = (\delta) = \{0; 3; 6; \delta; 3\delta\}.$$

The Teichmüller set $\Gamma_3(1) = \{0; 1; 8\}$, allows to write

$$GE(1) = \{a + b\theta : (a; b) \in \Gamma_3(1)\}$$

and

$$GE(2) = \{a + b\delta : (a; b) \in \Gamma_3(1)\}.$$

But $J(GE(1)) \neq J(GE(2))$. Indeed, if $J(GE(1)) = J(GE(2))$, then there exists $z \in GE(1)^\times$ such that $\theta = z\delta$. As

$$3 = \theta^2 = z^2\delta^2 = 6z^2.$$

It follows, $z^2 = (a + \theta b)^2 = a^2 + 2\theta ab$. Therefore, the equation $3 = 6z^2$ is equivalent to $3 = 6a^2$. Now, for all $a \in (\mathbb{Z}/9\mathbb{Z})^\times = \{1; 2; 4; 5; 7; 8\}$, we have $6a^2 = 6$. It is absurd.

Lemma 3.1. *Let R be the GE-ring of parameters (p, n, r, e, s) . Then there exists $\mathbf{v}$ in $U_r(\mathfrak{b}(e))$ such that $R = GE(\mathbf{v})$.*

Proof 2. *Let R be the GE-ring of parameters (p, n, r, e, s) . Then there exists $\mathbf{u} \in GR(p^n, r)^\times$ such that $R = GE(\mathbf{u})$. By the item 3 of Lemma 2.1., there exists*

$$(\gamma; \beta) \in \mathcal{R}_r(\mathfrak{b}(e)) \times \mathcal{R}_r(n - \mathfrak{b}(e)),$$

such that $\mathbf{u} = \gamma + p^{\mathfrak{b}(e)}\beta$ and $\gamma \in GR(p^n, r)^\times$. Since $\langle \delta \rangle \cdot \langle \eta \rangle = \Gamma_p(r)^*$, there exists $(\alpha, \mathbf{v}) \in \langle \eta \rangle \times U_r(\mathfrak{b}(e))$ such that $\gamma = \alpha\mathbf{v}$.

Now, $\mathbf{u} = \mathbf{v}(\alpha + p^{\mathfrak{b}(e)}\beta)$, where $\beta = \beta\mathbf{v}^{-1}$. We have

$$g := \alpha + p^{\mathfrak{b}(e)}\beta \in \mathcal{L}_e(R).$$

By Theorem 2.4, there exists $z \in R^\times$ such that $g = z^e$.

Since

$$GE(\mathbf{u}) = GR(p^n, r)[\theta]$$

with $\theta^e = p\mathbf{v}$ and $s = \min\{i \in \mathbb{N} : \theta^i = 0\}$. Thus, $J(GE(\mathbf{u})) = (\delta)$ where $\delta := z\theta$.

We have $\delta^e = p\mathbf{v}$ and $s = \min\{i \in \mathbb{N} : \delta^i = 0\}$. So $GE(\mathbf{u}) = GE(\mathbf{v})$. ■

The following lemma gives a fundamental condition for non-isomorphic pure GE-rings.

Lemma 3.2. *For each $\mathbf{u}$ and $\mathbf{v}$ in $U_r(\mathfrak{b}(e))$. Then*

$$\mathbf{u} \sim \mathbf{v} \Leftrightarrow \mathbf{u} = \sigma^i(\mathbf{v}),$$

for some $i \in \{0; 1; \dots; r-1\}$.

Proof 3. *Let $\theta := x + (x^e - p\mathbf{u} ; x^s)$ be a generator of $J(GE(\mathbf{u}))$. Then pure GE-rings $GE(\mathbf{u})$ and $GE(\mathbf{v})$ are isomorphic means by Lemma. 4 of [1], the existence of $(i; z) \in \{0; 1; \dots; r-1\} \times GE(\mathbf{u})^\times$ such that $(\theta z)^e = p\sigma^i(\mathbf{v})$ and $\theta^e = p\mathbf{u}$. Since $\mathbf{u}z^e = \sigma^i(\mathbf{v})$ and $\mathbf{u}, \sigma^i(\mathbf{v}) \in U_r(\mathfrak{b}(e))$, we have $z^e \in 1 + p^{\mathfrak{b}(e)}GR(p^n, r)$. Therefore,*

$$\begin{aligned} \mathbf{u} \sim \mathbf{v} &\Leftrightarrow \exists (i; \gamma) \in \{0; 1; \dots; r-1\} \times (1 + p^{\mathfrak{b}(e)}GR(p^n, r)) : \mathbf{u}\gamma = \sigma^i(\mathbf{v}), \text{ where } \gamma := z^e; \\ &\Leftrightarrow \exists (i; \gamma) \in \{0; 1; \dots; r-1\} \times (1 + p^{\mathfrak{b}(e)}GR(p^n, r)) : \mathbf{u}\gamma = \sigma^i(\mathbf{v}). \end{aligned}$$

Now, $\gamma \in (1 + p^{\mathfrak{b}(e)}GR(p^n, r)) \cap U_r(\mathfrak{b}(e)) = \{1\}$. ■

Let $\mathbf{u} \in U_r(\mathfrak{b}(e))$, we write $\mathbf{C}(\mathbf{u}) = \{\sigma^i(\mathbf{u}) : i \in \{0; 1; \dots; r-1\}\}$, the Frobenius class of $\mathbf{u}$ and $C_r(\mathfrak{b}(e))$ a complete set of Frobenius representative of $U_r(\mathfrak{b}(e))$.

Theorem 3.3. *Let $\Xi^*(p, n, r, e, s)$ be the set of pure GE-rings of parameters (p, n, r, e, s) up to isomorphism. Suppose that $(p-1) \nmid e$. Then the mapping*

$$\begin{aligned} GE : C_r(\mathfrak{b}(e)) &\rightarrow \Xi^*(p, n, r, e, s) \\ \mathbf{u} &\mapsto GE(\mathbf{u}) \end{aligned} \quad (3.3)$$

is bijective. Moreover,

$$|\Xi^*(p, n, r, e, s)| = \frac{1}{r} \sum_{i=1}^r \gcd(p^{\gcd(r,i)} - 1, e) p^{(\partial(e)-1)\gcd(i,r)}. \quad (3.4)$$

Proof 4. By Lemma 3.1, the mapping GE is bijection. Indeed, For each $\mathbf{u} \in U_r(\mathfrak{b}(e))$, there exists a unique $\mathbf{v}$ in $C_r(\mathfrak{b}(e))$ such that $GE(\mathbf{u}) = GE(\mathbf{v})$.

Now, we determine the size of $\Xi^*(p, n, r, e, s)$. Then we use the action of σ on $U_r(\mathfrak{b}(e))$ is given by:

$$\begin{aligned} \sigma : U_r(\mathfrak{b}(e)) &\rightarrow U_r(\mathfrak{b}(e)) \\ \varepsilon &\mapsto \sigma(\varepsilon). \end{aligned} \quad (3.5)$$

For each $1 \leq i \leq r$, we have:

$$\begin{aligned} \text{fix}(\sigma^i) &= \{\varepsilon \in U_r(\mathfrak{b}(e)) : \sigma^i(\varepsilon) = \varepsilon\}; \\ &= U_{r_i}(\mathfrak{b}(e)), \text{ where } r_i := \gcd(r, i). \end{aligned}$$

Thus by the Burnside's Lemma, the number of $\langle \sigma \rangle$ -orbits in $U_r(\mathfrak{b}(e))$ is

$$\frac{1}{|\langle \sigma \rangle|} \sum_{i=1}^r |\text{fix}(\sigma^i)| = \frac{1}{r} \sum_{i=1}^r \gcd(p^{r_i} - 1, e) p^{(\partial(e)-1)r_i}. \blacksquare$$

Thus, the mapping GE allows to determine up to isomorphism all pure GE-rings.

Example 5. Consider the pure GE-rings of parameters $(3, 2, 1, 2, 3)$. In according by Theorem Theorem 2.3, $\mathfrak{b}(2) = 1$. Then

$$C_1(1) = U_1(1) = \{1; 8\}.$$

By formula of Theorem 3.3, there are two non-isomorphism pure GE-rings of parameters $(3, 2, 1, 2, 3)$. Therefore, in the article [3], the GE-rings $r(1)$ et $r(8)$ are only non-isomorphism pure GE-rings of parameters $(3, 2, 1, 2, 3)$.

Example 6. Consider the GE-rings $GR(9, 2)[\theta]$ of parameters $(3, 2, 2, 18, 25)$ and $GR(9, 2) = (\mathbb{Z}/9\mathbb{Z})[\xi]$, with $\xi^2 = 5\xi + 1$.

In according by Theorem Theorem 2.3, $\mathfrak{b}(18) = 2$. Then

$$C_2(18) = U_2(2) = \langle \xi^4 \rangle = \{1; 8\}.$$

By formula of Theorem 3.3, there are 2 non-isomorphism pure GE-rings of parameters $(3, 2, 2, 18, 25)$, and the GE-rings of parameters $(3, 2, 2, 18, 25)$ up to isomorphism are $r(1)$, and $r(8)$

CONCLUSION

A pure Galois-Eisenstein ring of (p, n, r, e, s) is constructed from an element of the complete set of Frobenius representative of $U_r(b(e))$ and this construction are unique up to isomorphism. In general, the isomorphism problem for Galois-Eisenstein Rings stays open.
